1 Introduction

1.1 Problem Statement and Goals

Formal languages are likely to grow over time as they are getting more complex when their functionality is extended and more application cases are covered. On the one hand that leads to a more powerful language. However, on the other hand it becomes harder to understand the language and to implement it. Thus, it becomes harder for new users to use the language.

This problem can be addressed by dividing languages into smaller sub-languages that cover everything relevant to the specific use case. This could be done manually, but using this method is likely to raise errors or divergences from the original grammar.

Therefore, the approach considered in this report is to develop an application that is able to automatically extract sub-languages from a language. A sub-language should be specified by the user using the application.

This report focusses on the Thousands of Problems for Theorem Provers (**TPTP**) language for automated theorem proving. Sub-languages of interest are for example a grammar just for first-order clause normal form (**CNF**) or full first-order logic (**FOF**). The grammar of the language is provided in an extended Backus-Naur form (**EBNF**). The first step to divide the **TPTP** language in smaller sub-languages is to build a parser that parses the grammar of the **TPTP** language. The parser should build a parse tree that represents the grammar rules of the **TPTP** language. This parse tree should be visually presented to the user and the user can then choose which grammar rules should not be included in the desired sub-language. After the user specified the sub-language, the developed application should extract the sub-language from the **TPTP** language and present the sub-language in the same format as the original **TPTP** syntax. Also, comments present in the **TPTP** syntax should be maintained and associated with the corresponding rules in the reduced syntax.

1.2 Structure of the Report

This report is structured into six chapters. In the first chapter the research problem and goals of this research are stated. Then in chapter 2 the necessary background information for the following chapters 3 and 4 is provided. In chapter 3 the concept for the TODO APPLICATION is developed. Based on this, the implementation of the application is featured in chapter 4. In chapter 5 the results of the TODO reduced grammar is tested on a problem which is presented in a form corresponding to the reduced grammar. Chapter 6 sums up the results achieved in this research and offers an outlook for possible future research.

2 Background and Theory

[1] Compiler: Translate (high-level) programming language into machine language

Different phases for writing a compiler, phases are processed sequentially

2.1 TPTP Language

The Thousands of Problems for Theorem Provers (**TPTP**) is a library of problems for automated theorem proving (**ATP**). Problems within the library are described in the **TPTP** language. The **TPTP** language is a formal language and its grammar is specified in an **EBNF**. [2]

2.2 Backus-Naur form (**BNF**)

The Backus-Naur form (**BNF**) is a language to describe context-free grammars. In the Backus-Naur form (**BNF**) nonterminal symbols are distinguished from terminal symbols by being enclosed by angle brackets, e. g. $\langle TPTP_File \rangle$ denotes the nonterminal symbol $TPTP_File$. Productions are described using the " $::=$ " symbol and alternatives are specified using the "|" symbol. An example for a **BNF** production would be $TPTP_File ::= \langle TPTP_Input \rangle \mid \langle comment \rangle$. [3] Using this pattern of notation whole grammars can be specified.

The **EBNF** extends the **BNF** by with following rules:

- optional expressions are surrounded by square brackets.
- repetition is denoted by curly brackets.
- parentheses are used for grouping.
- terminals are enclosed in quotation marks.

[4]

2.3 Lexer

Lexing or a so called lexical analysis is the division of input into units so called tokens [5]. The input is a string containing a sequence of characters. Often, the lexer is generated by a lexer generator and not written manually. When writing the lexer manually TODO A lexer generator takes a specification of tokens as input and generates the lexer automatically. The specification is usually written using regular expressions. A regular expression describes a formal language and can be described by a finite automata. A formal language describes a set of words belonging to the language. These words are built over the alphabet of the language. Shorthands are common to simplify a regular expression. For example all alphabetic letters in lower and upper case are combined and represented by `[a-zA-Z]`. The same principle can be also be applied to represent a set of numbers. However, using not clearly defined intervals e.g. `[0-b]` is not common as it has different interpretations by different lexer generators and thus can lead to mistakes. [1]

A lexer needs to distinguish different types of tokens and furthermore decide which token to use if there are multiple ones that fit the input. [1]

A simple approach to build a lexer to to build an automata for each token definition and then test to which automata the input correspondends. However, this would be slow as all automatas need to be passed through in the worst case. Therefore, it is convenient to build a single automata that tests each token simultaneously. This automata can be build by combining all regular expressions by disjunction. Each final state from each regular expression is marked to know which token has been identified.

It is possible, that final states overlap as a consequence of one token being a subset of another token. For solving such conflicts a precedence of tokens can be declared. Usually the token that is being defined the earliest has a higher precedence and thus will be chosen if multiple tokens fit the input. [1]

Another task of the lexer is separating the input in order to divide it into tokens. Per convention the longest input that matches any token is chosen. [1]

2.4 Parser

2.4.1 Yacc

Building a syntax tree out of the generated tokens [1]

Parsing: establish relationship among tokens [5] Grammar: list of rules that defines the relationships [5]

Input: description of grammar [5] Output: parser [5]

2.4.2 PLY

Python Lex-Yacc (PLY) [6] is an implementation of lex and yacc in python. [LALR-parsing] consists of lex.py and yacc.py

lex.py tokenizes an input string

2.4.3 Nondeterministic Finite Automata

2.5 Python?

3 Concept

This chapter outlines the concept and the architecture of the software tool. First, the proposed software architecture is described.

3.1 Overview

3.1.1 Proposed Architecture

3.2 Lexer

The **TPTP** language is specified in a modified **EBNF**. Therefore there are deviations from standard **EBNF** (2.2) that need to be analysed to specify elementary tokens in the lexer. The standard **EBNF** uses only one production symbol (":="). In the **TPTP** language additional production symbols have been added. The following table 3.1 contains the production symbols used in the **TPTP** language.

Table 3.1: **TPTP** language production symbols [7]

Symbol	Rule Type
::=	Grammar
:==	Strict
::-	Token
:::	Macro

In the **TPTP** language specification square brackets not necessarily denote that an expression is optional. In token and macro rules they have the same meaning as in traditional **EBNF** and in grammar and semantic rules square brackets are terminals. Also, there are line comments in the **TPTP** language specification. A comment starts with the

4 Implementation

4.1 Lexer

-Definition of tokens

-Tabs and newlines ignored

-Newline would be helpful to identify comments because a comment is a newline followed by the percentage sign, as well as new rules if each rule would be represented in one line. However, there are rules that cover multiple lines. That is the main reason newlines are ignored.

-A comment is identified by the lexer as a percentage sign followed by an arbitrary character excluding "]". This is followed by any arbitrary character. A comment can not only be identified by a percentage sign as the percentage sign is also part of the terminal symbols. However, the percentage symbol when used as terminal symbol is embedded in square brackets.

Tokens: LGRAMMAR/TOKEN/STRICT/MACRO EXPRESSION:

Any arbitrary symbol that is the name of the rule followed by the symbol itself
(:==,:::,...)

Non terminal symbol:

A non terminal symbol starts with "<" and ends with ">". In between there is any arbitrary sequence of numbers, underscores and small or capital letters.

T SYMBOL:

COMMENT:

OPEN SQUARE BRACKET/CLOSE SQUARE BRACKET, OPEN/CLOSE PARENTHESIS, ALTERNATIVE SYMBOL, REPETITION SYMBOL:

-is recognized and represented by the symbol itself
